BACKGROUND

- Limited understanding of persistent POST-COVID symptoms.
 - Limited understanding of risk factors for developing POST-COVID symptoms.
- METHODS
- Curavista provided access to the ABCoV tool and their database. This database measures the course of subjective burden of disease thru a standardized online questionnaire.
 - ± 850 patients self-registered in Feb 2020- July 2020 (T0, first time registration), 161 patients applied to follow-up study a year after registration (T1).
 - Dataset of 161 patients at T0 and T1 were analyzed:
 - Demographics (sex, smoking status, age, weight, BMI, and exercise level), ABCoV overall score,
 - ABCoV scores per domain (symptom status, mental status and functional status)
 - Risk factors for Post-COVID were explored through linear regression analysis.

CURAVISTA ABCOV-TOOL

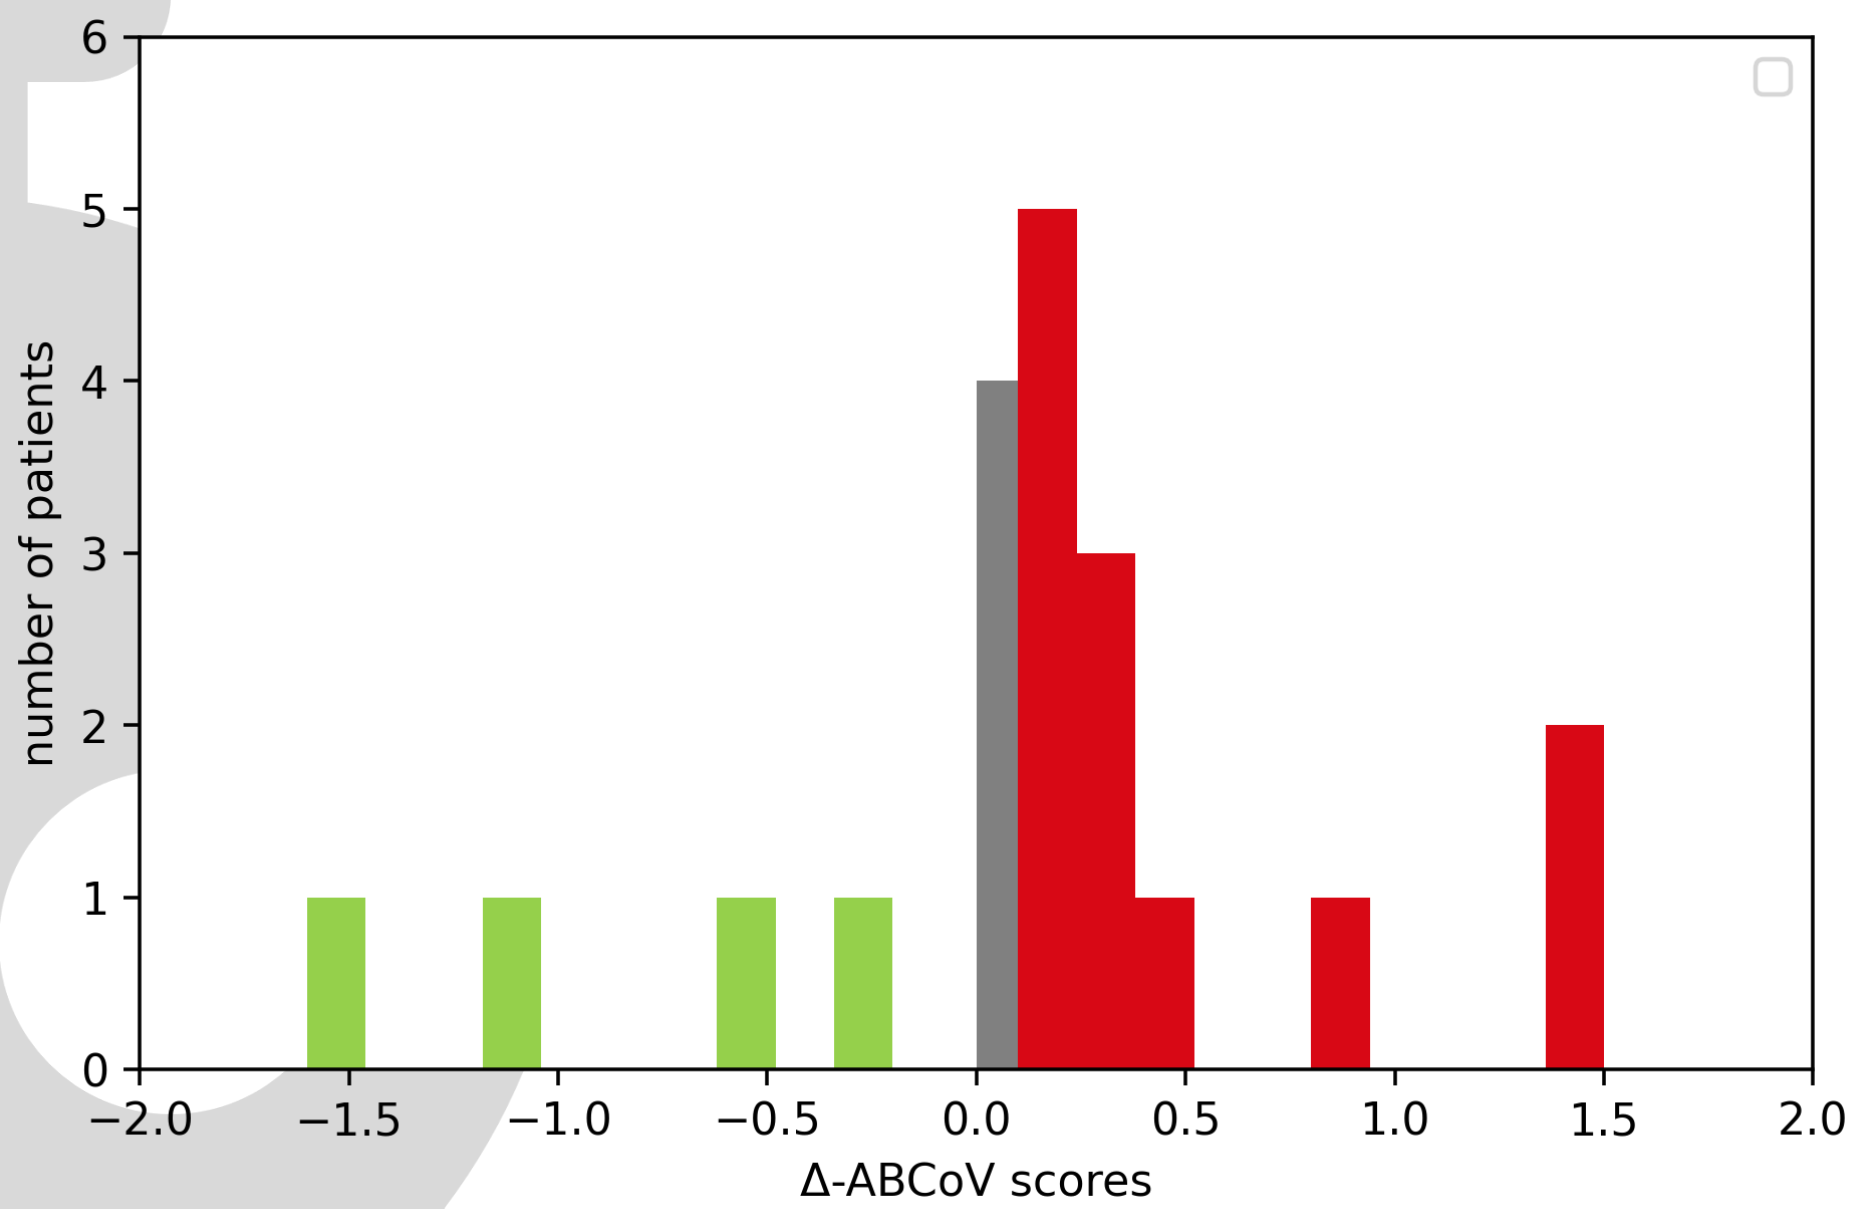

Persistent Post-COVID:
the first wave, one year after

RESULTS

- 88% reported no substantial complains at T1 (ABCoV <3).
- 12% reported substantial complaints (ABCoV ≥3) at T1 and categorized as persistent Post-COVID.
- In this subset, 60% had overall increase in complaints: 89% in mental status, 35% in functional status, and 39% in pulmonary status.
- Smoking, high BMI and lack of exercise at T0 are risk factors for developing long term symptoms.

DIFFERENCE IN TIME:
Δ-ABCOV SCORES FOR
ABCOV ≥3 GROUP AT T1

DISCUSSION/CONCLUSION

- Self registered COVID-19 infection.
- Possible bias induced by high drop-out rate.
- Behavioral aspects appear to be pivotal in primary prevention of long term Post-Covid symptoms.
